What is a *pushdown*?

Merriam-Webster

A store of data (as in a computer) from which the most recently stored item must be the first retrieved—called also *pushdown list* or *pushdown stack*.

We stick to this definition!

Why do we need them?

- Finite automata handle regular languages only
- Syntax of programming languages is context-free
 - Program text is of arbitrary length
 - Repeated nested bracket-like structures (e.g. arithmetic expressions)
- Pushdown automata offer infinite memory (even if LIFO structure)

Formal Definition of Pushdown Automaton

A pushdown automaton is a seven-tuple

$M = (Q, \Sigma, \Gamma, \delta, q_0, Z_0, F)$, where

- Q — finite set of states
- Σ — finite input alphabet
- Γ — finite alphabet of pushdown symbols
- δ — mapping $Q \times (\Sigma \cup \{\varepsilon\}) \times \Gamma \rightarrow 2^{Q \times \Gamma^*}$ transition function
- $q_0 \in Q$ — starting/initial state
- $Z_0 \in \Gamma$ — start symbol on the pushdown
- $F \subseteq Q$ — set of final states

Definition of Configuration

A *configuration* of PA M is a triple $(q, w, \alpha) \in Q \times \Sigma^* \times \Gamma^*$, where

- q — current state of the finite control
- w — unused input; the first symbol of w is under the reading head; if $w = \varepsilon$, then it is assumed that all the input has been read
- α — contents of the pushdown; the leftmost symbol is the topmost symbol; if $\alpha = \varepsilon$, then the pushdown is assumed to be empty

Move/Transition Definition

A *move/transition* by M is represented by the binary relation \vdash_M (or \vdash if M is understood) on configurations. We write

$$(q, aw, Z\alpha) \vdash (q', w, \gamma\alpha)$$

if $(q', \gamma) \in \delta(q, a, Z)$ for any $q \in Q$, $a \in \Sigma \cup \{\varepsilon\}$, $w \in \Sigma^*$, $Z \in \Gamma$, and $\alpha \in \Gamma^*$.

We can define relations \vdash^i , $i \geq 0$, \vdash^* , and \vdash^+ in the traditional way. \vdash^* and \vdash^+ stand for reflexive-transitive and transitive closures of \vdash , respectively.

Non-Deterministic PA](#)[Non-Deterministic PA](#)[Deterministic PA](#)[Examples](#)[Modifications of PA](#)[Non-Head-Moving PA](#)[One-Turn PA](#)[Atomic PA](#)[Conclusion](#)[References](#)

- Initial configuration: (q_0, w, Z_0) , $w \in \Sigma^*$
- Note: from the definition, it follows that there is no move possible if the pushdown is empty.*
- Final configuration, Ξ , $\Xi \in \{1, 2, 3\}$:
 - Empty pushdown: $(q, \varepsilon, \varepsilon)$, $q \in Q$
 - Final state: $(q_F, \varepsilon, \alpha)$, $q_F \in F$, $\alpha \in \Gamma^*$
 - Final state and empty pushdown: $(q_F, \varepsilon, \varepsilon)$, $q_F \in F$

Conclusion

References

- A word w , $w \in \Sigma^*$, is accepted by M if it makes transitions $(q_0, w, Z_0) \vdash^* \Xi$, where $\Xi \in \{1, 2, 3\}$ is the selected final configuration.

Language accepted by M

$L(M) = \{w \mid (q_0, w, Z_0) \vdash^* \Xi\}$, where $\Xi \in \{1, 2, 3\}$ is some (but fixed) of the final configurations.

How to construct a PA?

- Directly
- From a context-free grammar

Syntax Analysis

Virtual reconstruction of a particular derivation tree for the given grammar and sentence of the language.

Note: to make difference between end of the input tape and ignoring the input symbol we will use \$ to represent end of the input tape (empty input) and ϵ to denote that we do not read the symbol under the reading head and the reading head is not moved.

Top-Down Analysis

Virtual reconstruction of the derivation tree starts from the starting non-terminal of the respective context-free grammar.

Construction

Let $G = (N, T, P, S)$ be a context-free grammar then construct $M = (Q, \Sigma, \Gamma, \delta, q_0, Z_0, F)$ this way:

- $Q = \{q_0, q, q_F\}$
- $\Sigma = T \cup \{\$\}$
- $\Gamma = \{Z_0\} \cup T \cup N, \quad \{Z_0, \$\} \cap (T \cup N) = \emptyset$
- $F = \{q_F\}$
- For all $A \rightarrow \alpha \in P, A \in N, \alpha \in (N \cup T)^*$
add $(q, \varepsilon, A) \rightarrow \{(q, \alpha)\}$ to δ

For all $a \in T$ add $(q, a, a) \rightarrow \{(q, \varepsilon)\}$ to δ

Add $(q_0, \varepsilon, Z_0) \rightarrow \{(q, SZ_0)\}$ to δ

Add $(q, \$, Z_0) \rightarrow \{(q_F, \varepsilon)\}$ to δ

Example—Construction

CF Grammar

Let $G = (N, T, P, S)$, where: $N = \{S, E\}$, $T = \{(), +, i\}$,
 $P = \{S \rightarrow SS \mid E, E \rightarrow E + E \mid i \mid (E)\}$.

PA Construction

Let $M = (Q, \Sigma, \Gamma, \delta, q_0, Z_0, F)$, where:

- $Q = \{q_0, q, q_F\}$, $F = \{q_F\}$
- $\Sigma = T \cup \{\$\} = \{(), +, i, \$\}$
- $\Gamma = \{Z_0\} \cup T \cup N = \{S, E, (), +, i, Z_0\}$
- $\delta(q, \$, Z_0) \rightarrow \{(q_F, \varepsilon)\}$
 $\delta(q_0, \varepsilon, Z_0) \rightarrow \{(q, SZ_0)\}$
 $\delta(q, \varepsilon, S) \rightarrow \{(q, SS), (q, E)\}$
 $\delta(q, \varepsilon, E) \rightarrow \{(q, E + E), (q, i), (q, (E))\}$
 $\delta(q, (, ()) \rightarrow \{(q, \varepsilon)\}$
 $\delta(q, (),)) \rightarrow \{(q, \varepsilon)\}$
 $\delta(q, +, +) \rightarrow \{(q, \varepsilon)\}$
 $\delta(q, i, i) \rightarrow \{(q, \varepsilon)\}$

$\vdash (q, \$, Z_0)$	$\text{// } \delta(q, \$, Z_0) \rightarrow (q_F, \varepsilon)$
$\vdash (q_F, \$, \varepsilon)$	

Example—Derivation Reconstruction

Grammar “rules” used in the following order:

- ① $S \rightarrow SS$
- ② $S \rightarrow E$
- ③ $E \rightarrow E + E$
- ④ $E \rightarrow i$
- ⑤ $E \rightarrow i$
- ⑥ $S \rightarrow E$
- ⑦ $E \rightarrow (E)$
- ⑧ $E \rightarrow i$

It was **left derivation**, thus we get:

$$\begin{aligned}S &\Rightarrow SS \Rightarrow ES \Rightarrow E + ES \Rightarrow i + ES \Rightarrow i + iS \Rightarrow \\&\Rightarrow i + iE \Rightarrow i + i(E) \Rightarrow i + i(i)\end{aligned}$$

Bottom-Up Analysis

Reconstruction of the derivation tree starts from the symbols of the input sentence up to the starting non-terminal of the respective grammar.

Definition of Extended PA

An extended pushdown automaton is a seven-tuple $M = (Q, \Sigma, \Gamma, \delta, q_0, Z_0, F)$, where Q , Σ , Γ , q_0 , Z_0 , and F have the same meaning as for pushdown automaton.
 δ is defined as mapping $Q \times (\Sigma \cup \{\varepsilon\}) \times \Gamma^* \rightarrow 2^{Q \times \Gamma^*}$

 $\vdash (q_0, \$,)E(SZ_0)$
 $\vdash (q_0, \$, ESZ_0)$
 $\vdash (q_0, \$, SSZ_0)$
 $\vdash (q_0, \$, SZ_0)$
 $\vdash (q_1, \$, Z_0)$
 $\vdash (q_F, \$, \varepsilon)$

// $\delta(q_0, i, Z_0) \rightarrow (q_0, iZ_0)$
// $\delta(q_0, \varepsilon, i) \rightarrow (q_0, E)$
// $\delta(q_0, +, E) \rightarrow (q_0, +E)$
// $\delta(q_0, i, +) \rightarrow (q_0, i+)$
// $\delta(q_0, \varepsilon, i) \rightarrow (q_0, E)$
// $\delta(q_0, \varepsilon, E + E) \rightarrow (q_0, E)$
// $\delta(q_0, \varepsilon, E) \rightarrow (q_0, S)$
// $\delta(q_0, (, S) \rightarrow (q_0, (S)$
// $\delta(q_0, i, () \rightarrow (q_0, i()$
// $\delta(q_0, \varepsilon, i) \rightarrow (q_0, E)$
// $\delta(q_0, (), E) \rightarrow (q_0,)E)$
// $\delta(q_0, \varepsilon,)E() \rightarrow (q_0, E)$
// $\delta(q_0, \varepsilon, E) \rightarrow (q_0, S)$
// $\delta(q_0, \varepsilon, SS) \rightarrow (q_0, S)$
// $\delta(q_0, \varepsilon, S) \rightarrow (q_1, \varepsilon)$
// $\delta(q_1, \$, Z_0) \rightarrow (q_F, \varepsilon)$

Example—Derivation Reconstruction

Grammar “rules” used in the following order:

- ① $E \rightarrow i$
- ② $E \rightarrow i$
- ③ $E \rightarrow E + E$
- ④ $S \rightarrow E$
- ⑤ $E \rightarrow i$
- ⑥ $E \rightarrow (E)$
- ⑦ $S \rightarrow E$
- ⑧ $S \rightarrow SS$

It was **right derivation** in reverse order, thus we get:

$$\begin{aligned}S &\Rightarrow SS \Rightarrow SE \Rightarrow S(E) \Rightarrow S(i) \Rightarrow E(i) \Rightarrow \\&\Rightarrow E + E(i) \Rightarrow E + i(i) \Rightarrow i + i(i)\end{aligned}$$

Presented definition matches non-deterministic pushdown automata

Where is the non-determinism?

- $\delta(q, a, z) \rightarrow \{(q', \alpha), (q'', \beta), \dots\}$ — multiple choice
- $\delta(q, \varepsilon, z) \rightarrow \{\dots\}$ — ε matches always

All examples presented so far demonstrated non-deterministic pushdown automata

Formal Definition of Deterministic Pushdown Automaton

A deterministic pushdown automaton is a seven-tuple

$M = (Q, \Sigma, \Gamma, \delta, q_0, Z_0, F)$, where

- Q — finite set of states
- Σ — finite input alphabet
- Γ — finite alphabet of pushdown symbols
- δ — mapping $Q \times (\Sigma \cup \{\varepsilon\}) \times \Gamma \rightarrow Q \times \Gamma^*$ transition function
- $q_0 \in Q$ — starting/initial state
- $Z_0 \in \Gamma$ — start symbol on the pushdown
- $F \subseteq Q$ — set of final states

Configuration, move, final configuration, and accepted language defined the same way

Conclusion

References

Is the definition sufficient to ensure determinism?

No!

- Eliminated multiple choices,
- but the other option must be eliminated by **proper construction.**

Compare: $\delta(q, a, Z) \rightarrow (p, u)$ versus $\delta(q, \varepsilon, Z) = (p', u')$

Example 2' (ww^R , $w \in \{a, b\}^+$) — Discussion

Formal Pushdown
Automata

Dušan Kolář

No deterministic PA exists

Reason: it is impossible to denote the midpoint without additional information deterministically.

A non-ambiguous grammar exists though

$$S \rightarrow \varepsilon \mid aSa \mid bSb$$

Other features: can't be LL(1)

Question: can a deterministic PA be defined for language wcw^R , $w \in \{a, b\}^+$?

Example 3 — Introduction

Definition based on grammar description of the language:

$$P = \{ S \rightarrow SS \mid E, E \rightarrow E + E \mid i \mid (E) \}.$$

Problem: ambiguous grammar

Consider: $i + i + i$

$$S \Rightarrow E \Rightarrow E_1 + E_2 \Rightarrow E_{1.1} + E_{1.2} + E_2 \Rightarrow \dots$$

$$S \Rightarrow E \Rightarrow E_1 + E_2 \Rightarrow E_1 + E_{2.1} + E_{2.2} \Rightarrow \dots$$

We can make it non-ambiguous:

$$P = \{ S \rightarrow ES', S' \rightarrow \varepsilon \mid ES', E \rightarrow (E)E' \mid iE', E' \rightarrow \varepsilon \mid + E \}$$

Does it help?

Not for human... but for machine, maybe.

We need a modification of PA.

Head Does Not Move During Reading

Limiting feature: when recognizing symbol under the reading head, the head has to move.

Formal modification of transition function:

$$\delta : Q \times (\Sigma \cup \{\varepsilon\}) \times \Gamma \rightarrow Q \times \Gamma^* \times \{\mathcal{R}, \mathcal{M}\}$$

\mathcal{R} stays for reading the symbol under the reading head only
 \mathcal{M} stays for read&move (traditional behaviour)

Notation:

$$\delta(q, a, z) \rightarrow (q', \alpha)_R$$

$\delta(q, a, z) \rightarrow (q', \alpha)_M$ we write $\delta(q, a, z) \rightarrow (q', \alpha)$ if clear
where $q, q' \in Q, a \in \Sigma, z \in \Gamma, \alpha \in \Gamma^*$

Generally non-deterministic variant:

$$\delta : Q \times (\Sigma \cup \{\varepsilon\}) \times \Gamma \rightarrow 2^{Q \times \Gamma^* \times \{\mathcal{R}, \mathcal{M}\}}$$

// $\delta(q_0, \$, S') \rightarrow (q_0, \varepsilon)_R$

Example 3' — Discussion

Grammar features:

- Non-ambiguous
- LL(1)
- Not trivial to construct

How could we construct the PA?

- By straightforward reasoning from the grammar
—too difficult!
- By algorithm
 - See Aho, Sethi, Ullman: Compilers ... in References
 - LL(1) grammar is an input
 - Non-moving pushdown automaton necessary

Definition

Consider two consecutive moves made by a pushdown automaton, M . If during the first move M does not shorten its pushdown and during the second move it does, then M makes a turn during the second move. A pushdown automaton is *one-turn* if it makes no more than one turn with its pushdown during any computation starting from an initial configuration.

Theorem

One-turn pushdown automata characterize a family of linear languages.

Proof: see Harrison ... in References.

Definition

Modify δ as a mapping from $Q \times (\Sigma \cup \{\varepsilon\}) \times (\Gamma \cup \{\varepsilon\})$. During a move, an *atomic* pushdown automaton changes a state and, in addition, performs exactly one of the following actions:

- ① it pushes a symbol onto the pushdown
e.g. $\delta(q, \varepsilon, \varepsilon) \rightarrow \{(q', a)\}$
- ② it pops a symbol from the pushdown
e.g. $\delta(q, \varepsilon, a) \rightarrow \{(q', \varepsilon)\}$
- ③ it reads an input symbol
e.g. $\delta(q, a, \varepsilon) \rightarrow \{(q', \varepsilon)\}$

Example 1''' ($a^n b^n$, $n \geq 0$) — Definition

$$M = (Q, \Sigma, \Gamma, \delta, q_0, Z_0, F)$$

$$Q = \{q_0, q_a, q_{a'}, q_{a''}, q_b, q_F\}$$

$$\Sigma = \{a, b, \$\}$$

$$\Gamma = \{b, Z_0\}$$

$$F = \{q_F\}$$

$$\begin{aligned}\delta: \delta(q_0, a, \varepsilon) &\rightarrow (q_a, \varepsilon) \\ \delta(q_a, \varepsilon, Z_0) &\rightarrow (q_{a'}, \varepsilon) \\ \delta(q_{a'}, \varepsilon, \varepsilon) &\rightarrow (q_{a''}, b) \\ \delta(q_{a''}, \varepsilon, \varepsilon) &\rightarrow (q_0, Z_0) \\ \delta(q_0, b, \varepsilon) &\rightarrow (q_b, \varepsilon) \\ \delta(q_b, \varepsilon, Z_0) &\rightarrow (q_b, \varepsilon) \\ \delta(q_b, \varepsilon, b) &\rightarrow (q_0, \varepsilon) \\ \delta(q_0, \$, \varepsilon) &\rightarrow (q_F, \varepsilon) \\ \delta(q_F, \varepsilon, Z_0) &\rightarrow (q_F, \varepsilon)\end{aligned}$$

Features: deterministic, atomic \Rightarrow easy to implement

Example 1''' ($a^n b^n$, $n \geq 0$) — Discussion

Formal Pushdown
Automata

Dušan Kolář

Easy to implement \neq easy to define (algorithmically)

Quite a lot of steps ...

Automaton without movement of reading head is much more efficient ...

Importance in the formal theory

- simplicity of definition
- minimality of description
- ...

[Conclusion](#)

[References](#)

Conclusion

We have presented:

- Definition of pushdown automaton
- Connected terms: configuration, transition step, language accepted by PA
- Deterministic and non-deterministic variant
- Some modifications

Main importance in:

- Analysis of context-free languages
- Theoretical computer science
